

Problem Set # 7

Given: Monday, Oct. 29 **Recommended Completion Date:** Monday, Nov. 05

Do not submit for grading

Problem 1: Consider forced convection from a slender streamlined object in cross flow, as shown in the figure. The total surface area of the object is $A_s = 0.02 \text{ m}^2$. The surface of the object is maintained at a constant temperature of $T_w = 75^\circ\text{C}$ by means of electrical heating. The fluid temperature far from the object is also constant at $T_\infty = 25^\circ\text{C}$. Experiments yield the following data on the free stream velocity, U_∞ , and the total rate of heat loss, q_{total} :

Run 1: $U_\infty = 5 \text{ m/s}$; $q_{\text{total}} = 200 \text{ W}$

Run 2: $U_\infty = 24.02 \text{ m/s}$; $q_{\text{total}} = 600 \text{ W}$

- Calculate the heat transfer coefficient for Run 1 and Run 2.
- Calculate the total rate of heat loss from the object when $U_\infty = 13.46 \text{ m/s}$
- The following fluid properties are known: $\rho = 1 \text{ kg/m}^3$; $c_p = 1000 \text{ J/kg}\cdot^\circ\text{C}$; $k = 0.025 \text{ W/m}\cdot^\circ\text{C}$. The total friction drag in Run 1 is found to be 0.01 N . Calculate the dynamic viscosity of the fluid.

Ans.: (a) $h_1 = 200 \text{ W/m}^2\cdot^\circ\text{C}$; $h_2 = 600 \text{ W/m}^2\cdot^\circ\text{C}$; (b) $q_{\text{total}} = 400.02 \text{ W}$; (c) $\mu = 8.84 \times 10^{-6} \text{ kg/m}\cdot\text{s}$

Problem 2: A smooth flat plate is aligned with a cross flow of a fluid, as shown in the figure. The length of the plate in the flow direction is $L = 1 \text{ m}$, and its width is $W = 1 \text{ m}$. The plate is maintained at a constant temperature of $T_w = 50^\circ\text{C}$ by electrical heating. Only the top surface of the plate is exposed to the fluid flow, and the bottom surface is very well insulated. Experimental data show the followings:

Run 1: Laminar flow throughout: $U_{\infty,1} = 2 \text{ m/s}$; $T_{\infty,1} = 10^\circ\text{C}$; $\text{Drag}_1 = 8.4 \times 10^{-3} \text{ N}$; and $q_{\text{total},1} = 168 \text{ W}$

Run 2: $U_{\infty,2} = ? \text{ m/s}$; $T_{\infty,2} = 10^\circ\text{C}$; $\text{Drag}_2 = 0.5854 \text{ N}$; and $q_{\text{total},2} = 1170.8 \text{ W}$

- What is the free-stream velocity in Run 2? (hint: use Chilton-Colburn analogy)
- Additional measurements yield the following fluid properties: $\rho = 1 \text{ kg/m}^3$; $c_p = 1000 \text{ J/kg}\cdot^\circ\text{C}$. using Run 1 data and the Blasius-Pohlhausen similarity solutions (exact solutions), determine the dynamic viscosity, μ , and the thermal conductivity, k , of the fluid.
- In Run 2, what is the total rate of heat loss from the plate in the region $0.1 \text{ m} \leq x \leq 1.0 \text{ m}$?

Ans.: (a) $U_{\infty,2} = 20 \text{ m/s}$; (b) $\mu = 2 \times 10^{-5} \text{ kg/m}\cdot\text{s}$; $k = 0.02 \text{ W/m}\cdot^\circ\text{C}$; (c) $q_{\text{total}, 0.1 \text{ m} \leq x \leq 1 \text{ m}} = 1002.82 \text{ W}$.

Problem 3: A solid is convectively cooled by a cross flow in $U_\infty = (10+0.05 t)$ m/s, where t is the time in seconds after the initiation of the cooling. The volume of the solid is $8 \times 10^{-6} \text{ m}^3$ and its surface is $2 \times 10^{-3} \text{ m}^2$. The initial temperature of the solid, just before it is exposed to the convective cooling, is $T_i = 420^\circ\text{C}$. The free-stream temperature remains constant throughout the cooling process at $T_\infty = 20^\circ\text{C}$. The thermophysical properties of the fluid and the solid may be assumed to remain constant throughout the cooling process at the following values:

Fluid properties: $\rho = 1 \text{ kg/m}^3$; $c_p = 1000 \text{ J/kg-}^\circ\text{C}$; $\mu = 2 \times 10^{-5} \text{ kg/m-s}$; $k = 0.02 \text{ W/m-}^\circ\text{C}$

Solid properties: $\rho = 2000 \text{ kg/m}^3$; $c_p = 500 \text{ J/kg-}^\circ\text{C}$; $k = 400 \text{ W/m-}^\circ\text{C}$

Measurements indicate the followings: (i) the temperature inside the solid is (essentially) spatially uniform throughout the process; (ii) at $t = 0 \text{ s}$, $T = T_i = 420^\circ\text{C}$ and $dT/dt = -5.4^\circ\text{C/s}$; and (iii) at $t = 60 \text{ s}$, $T = 188.9^\circ\text{C}$ and $dT/dt = -2.6^\circ\text{C/s}$.

- Using the given data, and assuming that the general form $Nu = C Re^m Pr^n$ is instantaneously applicable throughout the cooling process determine the specific form of the variation of the heat transfer coefficient, h , with U_∞ .
- Predict the temperature of the solid at $t = 100 \text{ s}$.

Ans.: (a) $h = 17.08 \times (U_\infty)^{1/2}$; (b) $T = 108.63^\circ\text{C}$.
